Abstract

The efficacy of clinical hypnotherapy is now being established. Studies are using anecdotal information as the foundation on which to research into hypnotherapy. The research outcomes are demonstrating the effectiveness of hypnotherapy and calling for further research to determine the clinical range of hypnotherapy.

This literature review on the efficacy of clinical hypnotherapy has been commissioned by the Psychotherapists and Counsellors Federation of Australia (PACFA) which is a national peak body in the psychotherapy and counselling sector. It's member associations cover modalities such as body oriented psychotherapy; experiential therapy; expressive arts therapy; family/relationship therapy; general counselling and psychotherapy; hypnotherapy; integrative psychodynamic psychotherapy; psychoanalysis/psychoanalytic psychotherapy; and counsellor and psychotherapy educators.

The aim of this project is to develop an up-to-date (within Australia 2002 – 2012 and internationally 2007 - 2012) literature review which outlines the current literature pertaining to the effectiveness of hypnotherapy. The review is designed to inform the PACFA membership of the current and relevant data. With up to date data on the effectiveness of hypnotherapy counsellors and psychotherapists can assess the modality and gauge the value of hypnotherapy for their clients and within their practice and possibly explore hypnotherapy.

To achieve this outcome this review explored research literature to assist in determining the efficacy of clinical hypnotherapy treatment regimes. The review encompasses articles, books, book
chapters and other electronic data published in Australia over the last ten years and internationally in the last five years.

This comprehensive literature review and reference list has been undertaken using a systematic computer-assisted literature search of seven relevant databases and journals, books and websites.

The selected data was required to conform to the six predetermined evidence criterion provided by PACFA. Data was assessed to confirm it matched the selection criteria then specifically for relevance.

Research within hypnotherapy is demonstrating beneficial outcomes. More high quality research is required to validate hypnotherapy as a clinical modality across a broad range of treatments.
Introduction

There are undoubtedly many factors which impact on the availability of research. These are some factors although others may also exist. Research methodology is a component of study in university based programs. In Australia clinical hypnotherapy education is based in the vocational education training (VET) sector. The VET sector trains practitioners rather than researchers. University graduates are trained to undertake research. In the higher levels of VET training, practitioners are taught to read and analyse research and incorporate the research on at the practitioner or client level. It is self-evident that authors of clinical hypnotherapy research publications come from a variety of health disciplines which include medicine, psychology, dentistry and nursing. Hence it appears the educational sector in which clinical hypnotherapy training is housed has had an effect on the professions ability to produce researchers.

The fact that clinical hypnotherapy research is undertaken by health practitioners who obviously have acquired additional skills to their primary modality raises an additional issue. What levels of training have the researchers undertaken in clinical hypnotherapy? Whilst being professionals in their own discipline, have they undertaken courses which have given them adjunctive skills in clinical hypnotherapy rather than a primary set of skills? If we were to accept that the authors of publications are experts in their field and editors of specialist publications publish their articles, it is conceivable that the expert editors consider their articles significant. It is then noteworthy that the terms hypnosis and hypnotherapy are used interchangeably (Abramowitz, Barak, Ben-Avi, & Knobler, 2008; Alladin & Alibhai, 2007; Parliament of South Australia, 2009c) in a variety of professional articles.
This interchangeability was addressed (Frischholz, 1995; Frischholz, 1998) by the editor of the American Journal of Clinical Hypnosis yet the practice continues. With no universally accepted definition of hypnosis (Parliament of South Australia, 2009b) and confusion regarding the use of the terms hypnosis and hypnotherapy, it can be postulated that the profession requires clarification on these issues. Potential definitions of hypnotherapy/hypnosis appear in Appendix 2.

What relevance does the lack of clarification of the terms hypnosis and hypnotherapy, the fact that research methodology is not taught in the VET sector and authors of research articles have their primary skill set in health modalities other than clinical hypnotherapy? The relevance is to provide a reader with a framework in which to view the results of this literature review and to afford some possible lines of reasoning to comprehend the structure on which this research is based.

Methodology

A systematic literature review was undertaken using specialised hypnosis/hypnotherapy journals and electronic databases. Relevant publications which were unavailable electronically were retrieved manually. The searches were limited to Australian publications less than ten years old and international publications less than five years old. Controlled vocabulary, Medical Subject Headings (MeSH) descriptors and free text terms were identified and included in the search strategy. Only articles in the English language were included in the results (McCormack, 2010). An example of the search strategy is included as Appendix 1.

Relevant literature was identified by searching specialist hypnosis journals - American Journal of Clinical Hypnosis, Australia Journal of Clinical and Experimental Hypnosis, Australian Journal of Clinical Hypnotherapy and Hypnosis, Contemporary Hypnosis: the Journal of the British Society of
Experimental and Clinical Hypnosis, European Journal of Clinical Hypnosis, International Journal of Clinical and Experimental Hypnosis and Sleep and Hypnosis. The Australian Journal of Hypnosis was rejected as it was not peer reviewed. An outline of the search strategy appears in Appendix 3.

Additionally, Cinahl, Cochrane, Health Source Nursing/Academic, Medline, PsycARTICLES, PsycINFO, and Scopus were searched to include other relevant sources that may provide peer-reviewed articles which matched the selection criteria. Google Books, Google Scholar, Library of Congress, Lista, Pubmed, and Web of Science were used to support data retrieved if any additional information was required. The articles in English were searched using controlled vocabulary, Medical Subject Headings (MeSH) descriptors and free text terms and limited to predetermined Psychoterapists and Counsellors Federation of Australia (PACFA) parameters.

The data returned then was subjected to a two tier filtering process. The first round was to determine if the article was generally relevant to hypnosis research. The second tier determined the article’s relevance to the selection criteria. The selected articles were then reviewed for relevance and veracity of the research.

The search strategy returned 1623 articles of which 211 were duplicates. The search criteria returned numerous medical articles referring to the term ‘hypnotic’ in accordance with medical conditions involving sleep. These articles were filtered from the results at the first level.
Filtering Process

Database Search: 1623 Articles
- Cinahl: 288

Articles remaining

91 articles remained

Selection criteria

The relevant studies have provided data on hypnosis as a therapeutic intervention for either a specified condition or as an intervention for a symptom of a condition. The selection criteria included peer reviewed articles from Australia since 2002 and internationally since 2006 which examined the efficacy of hypnosis or clinical hypnotherapy. The types of research included were:

1. Meta-analysis of randomised controlled trials
2. Randomised controlled trials
3. Controlled studies without randomisation
4. Other types of quasi-experimental studies
5. Descriptive studies, such as comparative studies, correlation-based studies or case-control studies
6. Expert committee reports or opinions, clinical experience or respected authority, or both.

In the provided evaluation parameters there was no allowance for systematic reviews so these studies have been included in item 5 ‘Descriptive Studies’. The evidence level is depicted in the tables as ‘Ev lvl’.

The eligible research studies may or may not have used hypnosis as the primary treatment intervention, compared hypnosis with other interventions for the treatment outcome of a specified condition or compared different hypnosis techniques/methodologies.

There is an abundance of books written by experienced clinical hypnotherapists which outline techniques and give anecdotal case studies. To include these books in this literature review under item 6 would first require the determination of what is an expert which is outside the consideration of this literature review. Therefore only publications which were initially identified as conducting research and then were identified as expert opinion have been included.

Studies which included hypnosis as part of a treatment regime were included if they were able to provide a comment regarding the hypnosis component in their conclusion.

Studies written up more than once were excluded e.g. (Marc, Rainville, & Dodin, 2008; Marc et al., 2009)
Data Collection

The data collected was the result of a two-tier filtering of the data returned by the database searches. The first tier was to determine which publications broadly fulfilled the selection criteria. The second was to determine the level of evidence and health conditions which were treated by clinical hypnotherapy and then the relevant data were extracted.

The search criteria also captured the term 'hypnotic' which is a medical and pharmacological term relating to sleep. The articles which included 'hypnotic' (in the medical and pharmacological sense) were removed during the first reading of the 1693 articles.

91 articles were identified as matching the selection criteria. The lack of a similar methodological approach made it difficult to report on each study. Some studies used hypnosis as an adjunct to other therapeutic intervention whilst others used hypnosis as the primary intervention. Some studies were designed to deal with disorders whilst other studies treated the symptoms of disorders. Accurate comparisons between several studies referring to different disorders yet incorporating the same symptoms are difficult (Dale, Adair, & Humphris, 2010). For example whilst the health issues varied, such as irritable bowel syndrome, medical procedures, dental procedures and child birth, the symptom (or one of the symptoms) on which the article focussed was pain.

The following results are a synopsis of the findings of the available research. Many articles had several foci such as the primary condition and various symptoms. The review is based on the primary focus and other symptoms are acknowledged within the article. The articles have been grouped by their primary focus which may be a health condition (e.g. IBS) or a symptom (e.g. Pain). This has been done to aid the reading of these results. These groupings are anxiety, pain, depression, Irritable Bowel
Syndrome (IBS), Psychophysiological, Post-Traumatic Stress Disorder (PTSD) and 'Other'. General titles of 'Other' and 'Psychophysiological' have been adopted for articles which do not fit specified groupings. 'Other' includes studies which have only one article and include topics of Alexithymia, Emotional Numbing, Learning, Obesity, Self-efficacy, Sexual dysfunction, Sleep issues and Trauma. 'Psychophysiological' includes articles which refer to claims of hypnosis influencing some physiological process (not included in the major headings).

**Table 1: Article Groupings**

![Bar Chart](chart.png)
Findings

As cited (Alladin & Alibhai, 2007) the American Psychological Association Task Force determined hypnosis as an adjunct to cognitive-behaviour therapy (CBT) for obesity was ‘probably efficacious’ (Chambless et al., 1998). This Chambless and Hollon article is the only recent article which outlines a determination on the efficacy of hypnosis.

It is generally accepted that an evidence base is required for a treatment to be acknowledged as efficacious. The evidence base for hypnosis/clinical hypnosis/hypnotherapy/clinical hypnotherapy is being developed. Anecdotal information is fuelling research which in turn is demonstrating the accuracy of much of the anecdotal data and the efficacy of hypnotherapy. Whilst the research validates what was previously anecdotal claims we must be careful not to succumb to critics and realise that an absence of evidence is not evidence of absence (Shedler et al., 2010).

Overall the literature reports that hypnotherapy is providing beneficial client outcomes. A summary is presented and the full extract of the findings appears in Appendix 1.

Summary of anxiety findings

The key findings show hypnotherapy to be effective. Hypnotherapy was used to treat anxiety over a broad range of conditions (with adults and children) including alopecia, asthma, breast cancer, cancer management, dental treatments, emotional distress, medical procedures, phobias and pregnancy. The research has shown hypnotherapy to be effective.

Summary of depression findings
Five research articles have shown hypnotherapy may be a useful addition to existing treatment regimes. Insufficient research of high quality is available to adequately assess hypnotherapy on an individual basis. Whilst hypnotherapy appears to be effective, to make a definitive statement requires hypnotherapy to be researched as an individual or primary modality rather than in combination with other treatments such as CBT. One study reported hypnosis appeared to significantly improve depressive symptoms (p < .001).

**Summary of IBS findings**

The research into IBS has been based on previous research which falls outside the time parameters of this literature review (Gonsalkorale W M, Houghton L A, & Whorwell MD, 2002; Gonsalkorale, 2006). The eight studies included, report hypnotherapy is effective. Results outlining the benefits include mood elevation, short and long term benefits, substantial reduction in symptoms and consideration of hypnotherapy as a useful treatment. The small number of studies demonstrate positive results with hypnotherapy being accepted by patients. More research is required to provide further empirical data.

**Summary of ‘Other’ findings**

This grouping contains research which is not easily included in alternative groups. The included conditions are alexithymia, cancer, crime, emotional numbing, learning, obesity, self-efficacy, self-hypnosis recordings, sexual dysfunction, sleep issues, sports performance and trauma. Overall the studies supported the potential effectiveness of hypnotherapy with one commenting “hypnotherapy is an extremely valuable tool” and another finding effect sizes were not statistically significant. With the small number of studies available more research is required to validate these results.
Summary of Pain findings

27 of 28 articles reported beneficial responses to the use of hypnotherapy in a variety of pain related clinical settings. Article 28 reported that findings in hypnotherapy were inconclusive. Benefits across a wide range of patients (children, adolescents and adults) and conditions suggest that hypnotherapy has effectiveness in multiple domains. These domains range from pre and post-operative scenarios as well as acute and chronic cases. It is suggested that with further good quality research hypnotherapy can accepted for medical insurance and potentially in cases of work injuries.

Summary of Psychophysiological findings

Psychosomatic illness is well documented and the research of the use of hypnotherapy in the realm of psychophysiology has some data. Eleven studies in areas of analgesia, burn trauma, childbirth, dental procedures, enuresis, fibromyalgia, headaches and migraines, labour, lower back pain, multiple sclerosis, pre & post-operative care, procedural pain in children, psychophysiological immune function, sleep, Vestibulodynia and wound care have provided supportive research data. Overall the studies demonstrated hypnotherapy was a safe, clinically effective intervention that was statistically significant. More targeted hypnotherapy research is required to provide further data which can be evaluated along with existing research.

Discussion

Historically, the literature acknowledges acceptance of hypnosis as an effective intervention in medicine by the American Medical Association (AMA) in 1958 (Mackey, 2010). In 1998 American Psychological Association (APA) acknowledged that hypnosis was probably efficacious as an adjunct
for CBT. The question is what has happened since then to empirically validate hypnosis/hypnotherapy? Are we, as suggested by one author on pain (Milling, 2008), entering a golden era where meta-analytic and qualitative reviews provide the empirical evidence that hypnosis is effective?

Determining the effectiveness of hypnotherapy is a challenge. Hypnotherapy has often been used as part of a treatment regime rather than as the primary modality (Heitkemper, 2009; Sierpina, Astin, & Giordano, 2007). In those studies it is often difficult to separate the hypnotherapy component from the other range of treatments. Whilst separation is possible in some studies (Dhanani, Caruso, & Carinci, 2011) and the results support the effectiveness of hypnotherapy (Hunt & Ernst, 2011) the effectiveness of hypnotherapy can be best assessed when hypnotherapy is the primary treatment modality. Studies involving hypnotherapy and published in peer reviewed journals have provided the data on which this literature review is based. More good quality research data regarding hypnosis as an effective intervention (Dhanani, et al., 2011; Graci & Hardie, 2007) is required.

In a 1976 letter published in *The Lancet* a comment was made (Domínguez-Ortega & Rodríguez-Muñoz, 2010):

"*We were impressed by the ease of endoscopy and lack of distress to the patients using hypnorelaxation, and the patients were able to go home shortly after the procedure. Although the time required to prepare the patient beforehand is a disadvantage, this should not present a major problem in a well-organized endoscopy unit.*"

The anecdotal information from previous decades abounds and is supported by organisations such as the American Medical Association (1958) and comments regarding medical procedures (Sutherland & Knox, 1976) are also contained in the literature.
Studies show that the general public is interested and open to the use of hypnosis (Sohl et al., 2010). It is now up to the whole profession to meet this demand with research to empirically validate hypnosis treatments. This can be achieved by the fusion of the academic and practitioner factions of the profession which will provide access to research skills, practitioner skills and cohort sizes sufficient to complete empirically valid research.

The research clearly demonstrates hypnosis is effective for many conditions. The current challenge is to produce research data that explores the limits and further possibilities for hypnosis/hypnotherapy as a treatment modality. This would give support for hypnosis/hypnotherapy to be included in health management regimes.

Conclusion

The research articles that fell within the parameters of this review indicate positive client outcomes and potential effectiveness of hypnotherapy. It is apparent that much more research is required for true efficacy to be established. Based upon this body of literature and the researchers indication that hypnotherapy can be effective, it is suggested that hypnotherapy is already forming a beneficial part of some treatment regimes and should be considered within treatment management protocols for a wide range of conditions.

The recommendations for further research into hypnotherapy and the call for hypnotherapy to be included in treatment regimes will hopefully provide the impetus for future research. If future studies validate existing research findings then the conclusive evidence required to support the claim of effectiveness will be available. It is essential that the future studies employ rigorous methodology to enable hypnotherapy to be evaluated as an individual treatment modality.
Appendix 1: Publications supporting the findings.

**Anxiety**

Summary

The articles in this grouping all acknowledge that hypnosis is effective. The articles indicate that anecdotal data is growing and do go so far as to state that hypnosis improves the effect size in combination with CBT.

</table>
In conclusion, hypnotherapy offers patients with functional gastrointestinal disorders a 60% to 70% chance of substantial reduction in their symptoms. Patients receiving this form of treatment go back to work, exhibit less absenteeism, take less medication and consult their doctors less frequently. Hypnotherapy appears to be a valuable additional to an integrated care package.

Hypnotherapy has been shown to be effective in the treatment of IBS but so far, has failed to take into account both physiological and psychological symptoms.

This study highlighted the use of hypnosis as a treatment for IBS. Previous studies have demonstrated a relatively high success rate with hypnosis in the treatment of IBS. It is now being considered as a genuine and useful treatment which is gradually becoming acknowledged by medical authorities.

Other (includes Alexithymia, Emotional Numbing, Learning, Obesity, Self efficacy, Sexual dysfunction, Sleep issues and Trauma)

Summary

Although this grouping had a variety of symptoms and conditions one study showed small treatment effects whilst the other studies found hypnosis to be effective, highly effective and statistically significant.

Massicolle, 2008

| 40. | (Derbyshire, Whalley, & Oakley, 2009) | 4 | Pain | Fibromyalgia | 13 | Our results provide evidence that appropriate suggestion can relieve fibromyalgia pain with and without a formal hypnotic induction. These findings imply a therapeutic benefit from both hypnotic and nonhypnotic suggestion but with some additional benefit that is unique to suggestion following a hypnotic induction. |

| 41. | (Dhanani, et al., 2011) | 6 | Pain | | | The current literature on hypnosis for the treatment of pain demonstrates that the quality and quantity of research are insufficient to form definitive conclusions, and indicates a significant need for further scientific inquiry into this area. |

| 42. | (Elkins, Jensen, & Patterson, 2007) | 5 | Pain | | | The findings indicate that hypnosis interventions consistently produce significant decreases in pain associated with a variety of chronic-pain problems. Low patient numbers, lack of standardisation and long term follow-up inhibit definitive research evaluations. |

| 43. | (Filshie, 2008) | 2 | Pain | Pre & post operative | 200 | The present randomised controlled trial demonstrated that a brief hypnosis intervention before breast cancer surgery statistically significantly reduced intraoperative use of medications and postoperative patient reported surgical pain thus simultaneously reducing symptom burden and costs. |

| 44. | (Hammond, 2007) | 6 | Pain | Headaches and migraines | | Hypnosis has been shown to be efficacious with headache and migraine, free of the side effects, risks of adverse reactions, and the ongoing expense associated with the widely used medication treatments. Hypnosis should be recognized by the scientific, health care, and medical insurance communities as being an efficient evidence-based practice. |

<p>| 45. | (Huet, Lucas-Polomeni, Robert, Sixou, &amp; | 2 | Pain | Children (dental anaesthesia) | 30 | Significantly more children in the hypnosis group had no or mild pain. This study suggests that hypnosis may be effective in reducing anxiety and pain in children. |</p>

68. (Thompson, Steffert, Steed, & Gruzelier, 2010) 2 Pain Anaesthesia Self hypnosis 35 This study suggests that Virtual Reality has potential as an effective medium for those who have trouble engaging with interventions involving visualization or where the context for visualization training inhibits engagement (e.g., pain management).

69. (Bernardy, Fuber, Klose, & Hauser, 2011) 1 Pain Fatigue Depression Fibromyalgia 239 Efficacy of hypnosis/guided imagery to reduce pain was associated with low methodological study quality. Because of the methodological limitations we cannot fully recommend hypnosis/guided imagery for FMS therapy. The use of hypnosis/guided imagery as an adjunct to efficacious pharmacological and non-pharmacological treatments had been recommended by the German interdisciplinary guideline on FMS based on expert consensus.

70. (Martínez-Valero et al., 2008) 2 Pain Fatigue Depression Fibromyalgia 6 The results suggest that psychological treatment produces greater symptom benefits than the conventional medical treatment only, especially when hypnosis is added. On line with other studies, we conclude that hypnosis may be a useful tool to help people with fibromyalgia manage their symptomatology.

71. (Stoelb, Molton, Jensen, & Patterson, 2009) Pain Analgesia Fibromyalgia The results indicate that for both chronic and acute pain conditions: (1) hypnotic analgesia consistently results in greater decreases in a variety of pain outcomes compared to no treatment/standard care; (2) hypnosis frequently out-performs non-hypnotic interventions (e.g., education, supportive therapy) in terms of reductions in pain-related outcomes; and (3) hypnosis performs similarly to treatments that contain hypnotic elements (such as progressive muscle relaxation), but is not surpassed in efficacy by these alternative treatments.
Overall hypnosis interventions were considered safe, effective, clinically valuable and statistically significant. One study questioned the stability of short term gains over a longer period. The quality of research was queried so it was suggested that hypnosis be used with existing treatments. There was sufficient significance to suggest more research into links to the immune system.

<td>Using abreactive Ego State Therapy (EST), 36 patients meeting DSM-IV-TR and PTSD checklist (PCL) criteria were exposed to either 5–6 hours of manualized treatment or placebo in a single session. EST emphasizes repeated hypnotically activated abreactive “reliving” of the trauma experience combined with therapists’ ego strength. Both the placebo and EST treatment groups showed significant reductions in PTSD checklist scores immediately posttreatment (placebo: mean 17.34 points; EST: mean 53.11 points) but only the EST patients maintained significant treatment effect at 4-week and 16- to 18-week follow-ups. Abreactive EST appears to be an effective and durable treatment for PTSD inclusive of combat stress injury and acute stress disorder.</td>
</tr>
</tbody>
</table>
Hypnotherapy was grouped with supportive therapy, non-directive counselling and psychodynamic as only one trial existed in each therapy. A general comment of “psychological treatment can reduce traumatic stress symptoms” with specific comment regarding hypnotherapy.

Hypnotic procedures can serve as a useful adjunct to cognitive, exposure, and psychodynamic therapies. Today, hypnosis remains a promising, albeit far from definitively “proven,” technique for ameliorating posttraumatic symptoms.

Smoking

Summary

Hypnosis has long been regarded by the public as effective to quit smoking. Two studies concluded hypnosis and nicotine patches were beneficial, one remarked on insufficient evidence and one study concluded that hypnosis may help smokers quit.

Acupuncture and hypnotherapy are used by a large number of smokers as alternative smoking cessation aids. Our results suggest that these alternative aids may help smokers quit. Thus, we recommend that physicians promote the use of acupuncture and hypnotherapy.
Appendix 2: Hypnotherapy/hypnosis definitions

"Hypnotherapy" and "hypnosis" are yet to be defined (Parliament of South Australia, 2009b) however hypnotherapy is comprised of a distinct set of clinical skills (Parliament of South Australia, 2009a). Definitions have been proposed by a number of eminent practitioners/associations but universal acceptance of a definition is yet to be achieved.

The state of hypnosis has been compared to progressive relaxation (Hammond, 2010; Jensen & Patterson, 2006; Liossi, Santarcangelo, & Jensen, 2009; Stoelb, et al., 2009) in multiple articles yet is still deemed to be non-hypnotic.

A summary of some proposed definitions includes:

Hypnosis is the experience of a new awareness of self, based mainly on the use of fantasy or imagination, which facilitates a modified and concentrated attention that allows the subject to engage in new ways of thinking and of experiencing new possibilities of self-control. In the therapeutic context, it helps the client/patient to attain individual goals by accepting them as eminently possible and attainable. In hypnoanalysis, it also facilitates the connection of current distress with past experiences, helping the client/patient to have a greater awareness of factors that have shaped his or her personality. (Araoz, 2005)

Elias quoting Elman, Preston and Erickson (Elias, 2009)

Elman: Hypnosis is the use of suggestion, whether direct or indirect, to induce a heightened state of suggestibility in which there is bypass of the critical faculty of the mind, and selective attention to suggestions given.

Preston: Hypnosis is a state of awareness dominated by the subconscious mind.
**Erickson**: Hypnosis is a 'shrinking of the focus of attention.'

Hypnosis typically involves an introduction to the procedure during which the subject is told that suggestions for imaginative experiences will be presented. The hypnotic induction is an extended initial suggestion for using one’s imagination, and may contain further elaborations of the introduction. A hypnotic procedure is used to encourage and evaluate responses to suggestions. When using hypnosis, one person (the subject) is guided by another (the hypnotist) to respond to suggestions for changes in subjective experience, alterations in perception, sensation, emotion, thought, or behavior. Persons can also learn self-hypnosis, which is the act of administering hypnotic procedures on one’s own. If the subject responds to hypnotic suggestions, it is generally inferred that hypnosis has been induced. Many believe that hypnotic responses and experiences are characteristic of a hypnotic state. While some think that it is not necessary to use the word hypnosis as part of the hypnotic induction, others view it as essential. (Green, Barabasz, Barrett, & Montgomery, 2005)

We offer a definition of hypnosis (or trance) as an animated, altered, integrated state of focused consciousness, that is, controlled imagination. It is an attentive, receptive state of concentration that can be activated readily and measured. It requires some degree of dissociation to enter and become involved in imagined activity, enough concentration for an individual to maintain a certain level of absorption, and some degree of suggestibility to take in new premises. (Spiegel & Greenleaf, 2005)

Temes quoting Orne’s and Erickson’s hypnosis definition (Temes, 1999)

**Orne’s definition**: hypnosis is said to exist when suggestions from one individual seemingly alter the perceptions

**Erickson’s definition**: a procedure wherein changes in sensations, perceptions, thoughts, feelings, or behaviours are suggested
There is no generally accepted definition of hypnosis. Suffice it to say that hypnosis is a multidimensional phenomenon. Hypnosis includes: a set of expectancies and role enactments; induction of an altered state of consciousness or trance through a formal hypnotic induction; a heightened state of attentiveness to suggestions given by a hypnotist and/or to one’s own mental content in self-hypnosis; and a personality trait of hypnotizability. (Brown, 2007)

A meaningful definition is further complicated by ‘hypnotherapy’ and ‘hypnosis’ being used interchangeably (Abramowitz, et al., 2008; Alladin & Alibhai, 2007; Parliament of South Australia, 2009c) in a variety of professional articles. This interchangeability was addressed (Frischholz, 1995; Frischholz, 1998) by the editor of the American Journal of Clinical Hypnosis yet the practice continues. With no universally accepted definition of hypnotherapy or hypnosis (Parliament of South Australia, 2009b), and confusion regarding the use of the terms hypnotherapy and hypnosis, it can be postulated that the profession requires clarification on these issues.
